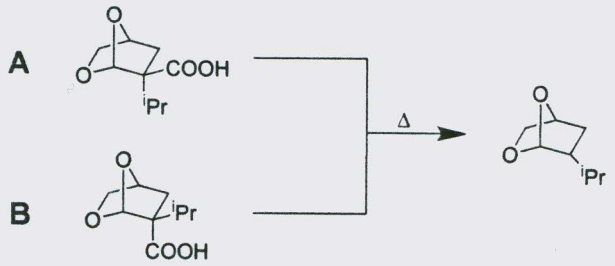
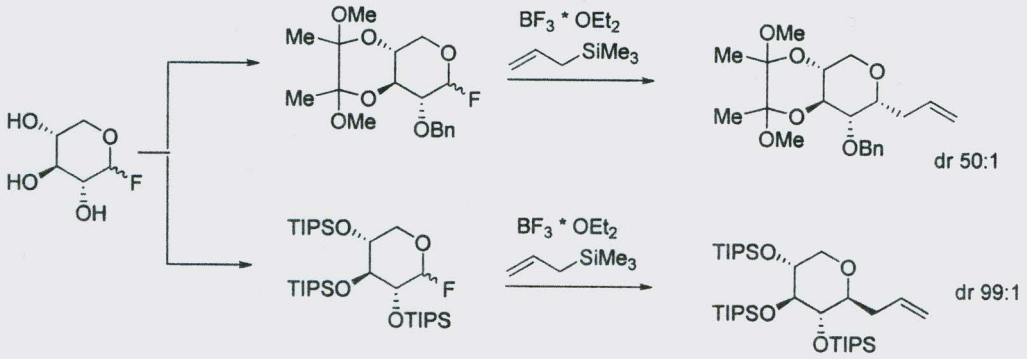
Organic Cume
March 8, 2013

Problems from the organic seminar:

1. One of the following isomers, either A or B, decarboxylates at a rate approximately 700 times faster than the other (there is no selectivity at the stereocenter with the isopropyl group). Draw mechanisms for the decarboxylation of each one, predict which reaction is faster and provide a rationale for your conclusion.





2. The steric course of the C-glycosidation may be controlled by the judicious choice of protecting groups. Using conformational drawings, provide a mechanism for each of the following C-glycosidations, including a rationale for the different configurations at C-1 of the products. TIPS = (triisopropyl)silyl.
